

Datatype

It is a classification that tells a computer what kind of value a variable holds and what operations can be performed on what data.

1. SINGLE VALUED DATATYPE : can hold only one value

int, float, complex, boolean

2. MULTI VALUED DATATYPE : can hold multiple value

str, list, tuple, set, dictionary.

Different ways to declare variable

1. $x = 2; y = 3$

2. $a = 2$

$b = 3$

3. $a, b, x, y = 2, 3, 4, 5$

[Here we should give value for all the variable initialised, else it will show error.

For eg :- $a, b, c = 2, 3$ is wrong

$a, b = 2, 3, 4$ is also wrong]
